Abstract:

Despite the great advances in the theory and applications of fractional calculus, some topics remain unclear making a systematic use difficult. In this paper the fractional differintegration definition problem is studied from a systems point of view. Both local (Grünewald-Letnikov) and global (convolutional) definitions are considered. It is shown that the Cauchy formulation should be adopted since it is coherent with usual practice in signal processing and control applications.

1. INTRODUCTION

Fractional calculus is an area of mathematics that deals with derivatives and integrals of non-integer order (i.e., real or, even, complex) that are joined under the name of differintegration. In the last decade, fractional calculus has been rediscovered by physicists and engineers and applied in an increasing number of fields [1-3], namely in the areas of signal processing, control engineering and electromagnetism [4-10, 18-20]. Despite the progress that has been made, several topics remain without a clear and concise formulation. Surprisingly, one of them is the definition of Fractional Differintegration (FD). In fact, there are several definitions that lead to different results [11-13], making the establishment of a systematic theory of fractional linear systems difficult. In facing this problem, we can adopt one of the following strategies:

- Choose a formulation, a priori, on the basis of a personal preference;

- Decide to work in a functional space where all the definitions give the same result [14]. However, this strategy is interesting only when solving differential equations with inputs in the same space;

- Choose formulations that assure a generalization of common and useful results or tools.

Bearing these ideas in mind, in this paper we will adopt the third point of view since it is the one that allows building a systematic theory of fractional linear system that resembles the theory of linear (integer order) systems.

The fact of dealing with non-integer order derivatives and integrals constitutes one of the major advantages in using fractional calculus, because solutions are general functions rather than being constrained to the exponential type. Consequently, we are interested in generalising the useful, and well known results, but there are noteworthy differences in this generalization. Integer-order derivatives depend only on the local behaviour of a function, while fractional derivatives depend on the whole history of the function [15]. Therefore, the problem is not just a simple matter of substituting the integer derivative by the fractional derivative; a proper definition of fractional derivative is needed. Moreover, it is important that the adopted definition preserves both the properties of the integer-order differintegration calculus and the fundamental concepts and properties of system theory.
As said previously there are several distinct definitions of $FD$ that are equivalent for a wide class of functions [1,13]. Nevertheless, from an engineering point of view most formulations reveal compatibility problems with the usual signal processing and systems theory practice. In fact, in signal processing, we often assume that signals have $\Re$ as domain and use the Bilateral Laplace and Fourier Transforms as key tools. Based on these tools, the important concepts of transfer function and frequency response are defined, with properties that we want to preserve in the fractional case. In this line of thought, different differintegration definitions from a common framework are considered in this article and compared in order to establish a practical mathematical tool. Without losing generality, we consider two possibilities for the definition of $FD$ in this work:

- An approach based on the generalisation of the usual derivative definition, that is, the Grunwald-Letnikov derivative and integral definitions,
- A global approach based on a convolutional formulation.

As known, any function can be defined in a space isomorphic to a space in which it has been defined in. Thus, it is possible to define the $FD$ through its properties in certain transformed space corresponding to some common transforms like the Laplace Transform ($LT$). Our starting point is the generalization of the well known property of the $LT$, corresponding to the time domain differentiation:

$$LT[D^\alpha f(t)] = s^\alpha F(s), \alpha \in \Re$$

where $D$ denotes the derivative, $f(t)$ is a signal with (two-sided) Laplace Transform $F(s)$ (2). If $\alpha > 0$ we have a fractional derivative; if $\alpha < 0$ it is a fractional integral. With this formulation the fractional integral and derivative are mutually inverse operations, which bring an important consequence: the fractional derivative and integral are inverse operations that commute (semigroup property):

$$D^\alpha \{D^\beta \} = D^{\alpha+\beta} = D^\beta \{D^\alpha \}, \alpha, \beta \in \Re$$

Unfortunately, this property is not valid in most differintegration definitions [1, 13], as it is the so-called Miller-Ross sequential derivative [1] and all the definitions that use a proper sub-set of $\Re$.

From a system point of view, we are looking for a “differintegrator” such that its transfer function is given by $s^\alpha$, provided that we have fixed a suitable branch cut line, since it is a multi-valued expression. There are infinite possibilities, but proceeding as Zavada [16], we choose the negative half-axis. It is clear that if we choose this branch cut line then we force the region of convergence of the $LT$ to be the right ($Re(s) > 0$) or the left ($Re(s) < 0$) half plane. This has an important consequence,

---

2 Exponential order ordinary function or distribution
namely that the differintegrator must be either causal or anti-causal, as in the usual negative integer case, contrarily to the common integer derivatives that are neither causal nor anti-causal (acausal).

In this line of thought, this paper is organized as follows. In sections two and three we discuss two distinct perspectives to differintegration, namely the Grünwald-Letnikov and the convolution approaches, respectively. Based on the previous results, section four shows an example common in signal processing and systems theory practice. Finally, section five draws the main conclusions.

2. GRÜNWALD-LETNIKOV DIFFERINTEGRATION

2.1. Derivatives

Grünwald-Letnikov derivatives are generalisations of the usual derivative definitions. Therefore, $s^\alpha$ ($\alpha > 0$) can be considered as the limit when $h \in \mathbb{R}^+$ tends to zero in the right hand sides of the following expressions:

$$s^\alpha = \lim_{h \to 0^+} \frac{(1 - e^{\alpha h})^\alpha}{h^\alpha}$$  \hspace{1cm} (3a)

$$s^\alpha = \lim_{h \to 0^+} \frac{(e^{\alpha h} - 1)^\alpha}{h^\alpha}$$  \hspace{1cm} (3b)

On the other hand, we can use the binomial series to obtain:

$$\frac{(1 - e^{\alpha h})^\alpha}{h^\alpha} = \frac{1}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} e^{-\alpha k h}, \quad \text{Re}(s) > 0$$  \hspace{1cm} (4a)

$$\frac{(e^{\alpha h} - 1)^\alpha}{h^\alpha} = \frac{(-1)^\alpha}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} e^{\alpha k h}, \quad \text{Re}(s) < 0$$  \hspace{1cm} (4b)

In the integer order cases, the right sides in the above expressions are identical. With these formulae, we can write:

$$s^\alpha = \lim_{h \to 0^+} \frac{1}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} e^{-\alpha k h}, \quad \text{Re}(s) > 0$$  \hspace{1cm} (5a)

$$s^\alpha = \lim_{h \to 0^+} \frac{(-1)^\alpha}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} e^{\alpha k h}, \quad \text{Re}(s) < 0$$  \hspace{1cm} (5b)
Note the right hand sides regions of convergence. This means that (5a) and (5b) lead to causal and anti-causal derivatives, respectively. When inverted to the time domain, these expressions correspond, respectively, to (3):

\[ D_+^\alpha(t) = \lim_{h \to 0^+} \frac{1}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} \delta(t - kh) \]  

\[ D_-^\alpha(t) = \lim_{h \to 0^+} \frac{(-1)^\alpha}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} \delta(t + kh) \]  

where \( \delta(t) \) is the Dirac delta impulse.

Let \( f(t) \) be a limited function and \( \alpha > 0 \). The convolution of (6a) and (6b) with \( f(t) \) leads to the Grünwald-Letnikov forward and backward derivatives:

\[ f_+^{(\alpha)}(t) = \lim_{h \to 0^+} \frac{1}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} f(t - kh) \]  

\[ f_-^{(\alpha)}(t) = \lim_{h \to 0^+} (-1)^\alpha \frac{1}{h^\alpha} \sum_{k=0}^{\infty} (-1)^k \binom{\alpha}{k} f(t + kh) \]  

Both expressions agree with the usual derivative definition when \( \alpha \) is a positive integer. Moreover, expression (7a) corresponds to the left-hand sided Grünwald-Letnikov fractional derivative while (7b) has the extra factor \( (-1)\alpha \), when compared with the right-hand sided Grünwald-Letnikov fractional derivative [13]. Therefore, (7a) and (7b) should be adopted for right and left signals \(^4\), respectively. In [13] the convergence properties of the above series are studied. It is noteworthy that we can have the forward derivative without the backward one existing and vice-versa. For example, let us apply both definitions to the function \( f(t) = e^{at} \). If \( a > 0 \), expression (7a) converges to \( f_+^{(\alpha)}(t) = a^\alpha e^{at} \), while (7b) diverges. On the other hand, if \( f(t) = e^{-at} \) equation (7a) diverges while (7b) converges to \( f_-^{(\alpha)}(t) = (-a)^\alpha e^{-at} \).

Within these definitions, we can apply (7a) or (7b) successively for different values of \( \alpha \), leading also to a multi-step derivative \( \mathcal{D}^\alpha = \mathcal{D}^\beta \mathcal{D}^\gamma \mathcal{D}^\mu \ldots \mathcal{D}^\lambda \), with \( \alpha = \beta + \gamma + \mu + \ldots + \lambda \). This means that we

---

\(^3\) We do not address the problem of the convergence of the series here [see [17]].

\(^4\) We say that \( x(t) \) is a right [left] signal if \( \xi(-\infty) = 0 \) [\( x(+\infty) = 0 \)].
have infinite ways of performing a fractional derivative. However, the order in which the fractional differential operators are concatenated is relevant. This is a very important matter that has originated a lot of problems mainly when solving fractional differential equations under non zero initial conditions [9]. When $\alpha$ is negative the series is divergent, in general, and an alternative definition needs to be derived as shown in the next section.

2.2. Integrals

The expressions for the Grünwald-Letnikov derivatives are not useful for integration [13]. We should expect this because $\frac{h}{1 - e^{-sh}} \approx \frac{1}{s}$ is a poor approximation and, in fact the bilinear expression

$$\frac{h}{2} \frac{1 + e^{-sh}}{1 - e^{-sh}} \approx \frac{1}{s}$$

is superior. Therefore, we can adopt the second approximation to define the fractional integration, leading to a more suitable form for the fractional integral computation.

For small $h \in \mathbb{R}^+$:

$$\frac{1}{s^\alpha} \approx \left(\frac{h}{2} \frac{1 + e^{-sh}}{1 - e^{-sh}}\right)^\alpha = \frac{h^\alpha}{2^n} \sum_{n=0}^{\infty} C_n^\alpha e^{-sh}, \quad \text{Re}(s) > 0 \quad (8)$$

where

$$C_n^\alpha = \sum_{k=0}^{n} (-1)^k \binom{\alpha}{k} \binom{n-k}{\alpha} \quad n \geq 0 \quad (9)$$

is the convolution of the coefficients of two binomial series. We can give another form to (9). As

$$\binom{a}{k} = (-1)^k \frac{(-a)_k}{k!} \quad (10)$$

where $(a)_n = a(a+1)\ldots(a+n-1)$ is the Pochhammer symbol and remarking that $n! = (-1)^k (-n)_k (n-k)!$ and $(a)_n = (-1)^k (-a+n+1)_k (a)_{n-k}$ for $k \leq n$, we obtain:

$$C_n^\alpha = (-1)^n \frac{(-\alpha)_n}{n!} \sum_{k=0}^{n} \frac{(\alpha)_k (-n)_k (-1)^k}{(-\alpha - n + 1)_k k!} \quad (11)$$

or

$$C_n^\alpha = (-1)^n \frac{(-\alpha)_n}{n!} \mathbf{2F}_1[(\alpha,-n,-\alpha - n + 1,-1] \quad (12)$$

The anti-causal case is similar.

\[5\]
where \(_{2}F_{1}\) is the Gauss Hypergeometric function \([2]\). Consequently, approximation (8) leads to a Grünwald-Letnikov like fractional integral of order \(\alpha\) for a function \(f(t)\):

\[
f^{(\alpha)}(t) = \lim_{h \to 0^+} h^{\alpha} \sum_{n=0}^{\infty} C_{n}^{\alpha} f(t - nh), \quad \alpha < 0
\]  

(13)

For causal signals and \(h > 0\), the series in (7a) and (13) become finite summations. The formulation (12) is interesting because it allows us to compute \(C_{n}^{\alpha}\) recursively. In fact, although the Gauss hypergeometric function does not have a closed form for those arguments it satisfies the following recursion \([6]\):

\[
f(n) = \frac{2\alpha}{\alpha+n-1}f(n-1) + \frac{(n-1)(n-2)}{(\alpha+n-1)(\alpha+n-2)}f(n-2)
\]  

(14)

with \(f(0) = 1\), and \(f(1) = 2\).

3. CONVOLUTIONAL DIFFERINTEGRATION

Here we address the linear system case (the Differintegrator) that has \(s^{\alpha}\) - with \(\text{Re}(s) > 0\) or \(\text{Re}(s) < 0\) – as Transfer Function. To find its Impulse Response, we look for the inverse Laplace transform of \(s^{\alpha}\delta^{(\alpha)}(t)\), with \(\alpha \in \mathbb{R}\). So the differintegration of a signal \(f(t)\) is given by the convolution of \(f(t)\) with \(\delta^{(\alpha)}(t)\). To present this convolutional differintegration definition, we introduce the following distributions:

\[
\delta^{(-\nu)}_{\pm}(t) = \pm \frac{t^{-\nu}}{\Gamma(\nu)} u(\pm t), \quad 0 < \nu < 1
\]  

(15)

and

\[
\delta^{(n)}_{\pm}(t) = \begin{cases} \pm \frac{t^{n-\nu}}{\Gamma(n)} u(\pm t) & \text{for } n < 0 \\ \delta^{(n)}(t) & \text{for } n \geq 0 \end{cases}
\]  

(16)

where \(n \in \mathbb{Z}\), \(\delta^{(\alpha)}(t)\) is the \(\alpha\) differintegrator of \(\delta(t)\) and \(u(t)\) is the Heaviside unit step.

The differintegrations usually used \([2]\) can be classified as right and left sided, respectively:

\[
\int^\alpha_{r}(t) = [f(t) u(t - a)] * \delta^{(n)}_{+}(t) * \delta^{(-\nu)}_{+}(t)
\]  

(17a)

\[
\int^\alpha_{l}(t) = [f(t) u(b - t)] * \delta^{(n)}_{+}(-t) * \delta^{(-\nu)}_{+}(-t)
\]  

(17b)
The orders are given by \( \alpha = n - \nu \), \( n \) being the least integer greater than \( \alpha \) and \( 0 < \nu < 1 \). In particular, if \( \alpha \) is integer then \( \nu = 0 \) \( (6) \). We must remark that, from our point of view, only the cases \( a = -\infty \) and \( b = +\infty \) cases are acceptable. Otherwise, we are incorporating signal characteristics into a definition that we think is wrong. We must state a definition valid for all functions. In other words, the definition must be the same independently of the signal being differintegrated. With this in mind, we rewrite (17a) and (17b) as:

\[
\begin{align*}
\mathcal{F}_r^{(\alpha)}(t) &= f(t) * \delta_+(n) * \delta_+^{(-\nu)}(t) \\
\mathcal{F}_l^{(\alpha)}(t) &= f(t) * \delta_+^{(-n)}(-t) * \delta_+^{(-\nu)}(-t)
\end{align*}
\]  

(18a)

(18b)

The \( LT \) of (18a) and (18b) are \( s^\alpha X(s) \) and \( (-s)^\nu X(s) \), respectively, that differ on the factor \( (-1)^\alpha \). This means that it is not a backward differintegration and therefore it is unsuitable. From these considerations, we are led to the expressions for the forward and backward differintegrations with general format given by:

\[
\begin{align*}
\mathcal{F}_r^{(\beta)}(t) &= \delta_+(n) \left\{ f(t) * \delta_+^{(-\nu)}(t) \right\} \\
\mathcal{F}_l^{(\beta)}(t) &= \left\{ f(t) * \delta_+^{(-n)}(t) \right\} * \delta_+^{(-\nu)}(t) \\
\mathcal{F}_l^{(\beta)}(t) &= \left\{ \delta_+^{(-n)}(t) * \delta_+^{(-\nu)}(t) \right\}, n \in \mathbb{Z}, 0 \leq \nu < 1
\end{align*}
\]  

(20a)

(20b)

(20c)

We must remark that (20a) corresponds to a \( \nu \) order integration followed by an \( n \) integer order derivative, while in (20b) we have the reverse situation. Concerning equation (20c), the convolution inside brackets is a generalised function given by \( [2,18,21] \):

\[
\delta_+^{(\beta)}(t) = \left\{ \delta_+^{(n)}(t) * \delta_+^{(-\nu)}(t) \right\} \frac{t^{\beta-1}}{\Gamma(-\beta)} u(t), \ \beta = n - \nu
\]  

(21)

---

6 All the above formulae remain valid in the case of integer integration, provided that we put \( \delta_0^0(t) = \delta(t) \).
which can be considered as the Impulse Response of the fractional differintegrator. With it we can perform the computation in one step. Moreover, this formulation is a generalization of the well-known Cauchy integral [12,13]. It is not difficult to obtain the corresponding backward formulations.

4. SELECTING A DIFFERINTEGRATION

From previous sections it seems clear that:

- the above three formulations are equivalent when looked from the LT point of view.
- contrary to the Grünwald-Letnikov differintegration and (20c), the computation is done in two steps in (20a) and (20b).

We can combine all the differintegrations in the sense that we can decompose the order as $\beta = \beta_1 + \beta_2 + \beta_3 + \ldots + \beta_n$ and use any method to compute the $\beta_i$ ($i = 1, \ldots, n$) differintegration.

This can lead us to a complicated situation or to results that are far from the expected. Consider the following problem. We want to check if $x(t)$ is the solution of the differential equation $x^{(3/2)}(t) + a x^{(1/3)}(t) + b x^{(1/5)}(t) = 0$, $a, b \in \mathbb{R}$, for $t > 0$. We have the options:

a) In the Riemann-Liouville formulation (20a), we have to compute 3 integrals and 4 integer derivatives. In fact, if we want to compute the above derivatives sequentially we have to do the following sequence of computations:

$$x^{(1/5)}(t) = D_{\frac{1}{5}} x(t) \rightarrow x^{(1/3)}(t) = D_{\frac{1}{3}} x^{(1/5)}(t) \rightarrow x^{(3/2)}(t) = D_{\frac{3}{2}} x^{(1/3)}(t).$$

Figure 1 – steps and initial conditions in the Riemann-Liouville definition

b) In the Caputo formulation (20b) we have the same operations but the derivatives and integrations are in reverse order:

$$x^{(1/5)}(t) = D_{\frac{1}{5}} x(t) \rightarrow x^{(1/3)}(t) = D_{\frac{1}{3}} x^{(1/5)}(t) \rightarrow x^{(3/2)}(t) = D_{\frac{3}{2}} x^{(1/3)}(t).$$

Figure 2 – steps and initial conditions in the Caputo definition

c) In the Cauchy definition (20c) we have 3 fractional derivatives:

$$x^{(1/5)}(t) = D_{\frac{1}{5}} x(t) \rightarrow x^{(1/3)}(t) = D_{\frac{1}{3}} x^{(1/5)}(t) \rightarrow x^{(3/2)}(t) = D_{\frac{3}{2}} x^{(1/3)}(t).$$

Figure 3 – steps and initial conditions in the Cauchy definition
On the other hand, we must remark that each time we perform an integer order derivative, we are inserting initial conditions that may be meaningless in the problem at hand. In the sequence of operations presented above, we introduce the following initial conditions [1,2,14]:

a) Riemann-Liouville case: \( D^{\alpha+1/2} x(t) \big|_{t=0^+} \), \( D^{\alpha+1/3} x(t) \big|_{t=0^+} \), \( D^{\alpha+1/2} x(t) \big|_{t=0^+} \), and \( D^{\alpha+1/2} x(t) \big|_{t=0^+} \). To understand these results, we only have to remember that \( D[\delta(t)] = D[f^{(0)}(t)]u(t) + f^{(0)}(0^+)\delta(t) \).

b) Caputo case: \( x(t) \big|_{t=0} \), \( D^{\alpha+1/2} x(t) \big|_{t=0} \), \( D^{\alpha+1/3} x(t) \big|_{t=0} \), and \( D^{\alpha+1/2} x(t) \big|_{t=0} \). In this case, the fractional integration does not insert an initial condition, contrarily to the integer order derivative. Then, we have \( D^\alpha[f(t)u(t)] = D^\alpha[f(t)u(t) + f(0^+),\delta(t)] \), leading to the result.

c) Cauchy case: \( x(t) \big|_{t=0} \), \( D^{\alpha+1/2} x(t) \big|_{t=0} \), and \( D^{\alpha+1/3} x(t) \big|_{t=0} \). This result directly from the equation. Of course, we can use other initial conditions by specifying other derivatives, even not “visible” in the equation. For example, we can write: \( x^{(1/2)}(t) + 0.x^{(1)}(t) + 0.x^{(1/2)}(t) + a x^{(1/3)}(t) + b x^{(1/3)}(t) = 0 \) and insert the corresponding initial conditions [14].

To exemplify, consider a simple circuit with two fractional capacitors [22]:

Figure 4 – Electrical circuit using fractional capacitors

The subscripts in C point the integration order, say. The impedance corresponding to a given capacitor is given by \( \frac{1}{(j\omega C_i)} \) with \( i = \alpha \) or \( \beta \) [3]. We will assume that \( \beta \geq \alpha \). It is not hard to show that the input-output relation is given by:

\[
a_3 D^{\alpha+1/2} v_c(t) + a_2 D^{\alpha} v_c(t) + a_1 D^{\alpha} v_c(t) + v_c(t) = v_i(t)
\]

and, also

\[
a_3 D^{\alpha+1/2} v_c(t) + a_2 D^{\alpha} v_c(t) + a_1 D^{\alpha} v_c(t) + v_c(t) = b D^{\beta} v_i(t) + v_i(t)
\]

with: \( a_3 = RC_\alpha \), \( a_2 = 2RC_\beta \), \( a_1 = R^2C_\alpha C_\beta \) and \( b = RC_\beta \).

Assume that if \( t = 0 \), the circuit is open in the sense that the currents are zero, but the capacitors have charge. At a given instant, the circuit is closed and a given input \( v_i(t) \) is applied to it. To compute \( v_c(t) \) and \( v_i(t) \) it seems natural to use the voltage at both the capacitors as initial conditions [3]. This makes use of Riemann-Liouville definition invalid, since it uses \( D^{\alpha+1/2} v_c(t) \big|_{t=0} \) and \( D^{\alpha+1/2} v_c(t) \big|_{t=0} \), which does not make any physical sense. On the other hand, assume that you apply a given input and let the circuit reach a steady state. At a given instant, \( T \), we let \( v_i(t) = 0 \), for \( t \geq T \). Now, it seems natural to accept \( D^{\alpha} v_c(t) \big|_{t=T} \) and \( D^{\beta} v_c(t) \big|_{t=T} \) as initial conditions. Again both the Riemann-Liouville and Caputo

\[\text{For } v_c(t) \text{ the situation is similar.}\]
definitions use other initial values that are not accessible. The first uses $D^{\alpha-1}v(t)|_{t=T}$ and $D^{\beta-1}v(t)|_{t=T}$ and the second uses $Dv(t)|_{t=T}$ and $D^2v(t)|_{t=T}$.

From these considerations we must conclude that Cauchy’s is the most useful differintegration, because:

- It does not need superfluous derivative computations
- It does not insert unwanted initial conditions
- It is more flexible and allows a sequential computation

5. CONCLUSIONS

In this paper two general frameworks for differintegration definitions were presented, namely local and global formulations. The first approach is the Grünwald-Letnikov definition that is a generalisation of the common derivative. It was proposed a new definition for the integral case suitable for numerical algorithms. The global definition has a convolutional format. Among the approaches within this formulation the Cauchy definition was chosen because it enjoys all the characteristics required in signal processing and control applications.
