Abstract

Purpose – This paper aims to investigate the ways in which “non-collaborative co-creation” can affect brand equity as perceived by independent observers. It reports a study of the different effects on that perception attributable to non-collaborative co-creation that takes the form of either “brand play” or “brand attack” and is executed either by established artists or mainstream consumers.

Design/methodology/approach – A 2 x 2 between-subjects experiment (brand play versus brand attack; consumer versus artist) measured observers’ perception of brand equity before and after exposure to purpose-designed co-created treatments.

Findings – Non-collaborative co-creation has a negative effect on observers’ perceptions of brand equity and brand attack, causing a stronger dilution of brand equity than brand play. Artists either mitigate the dilution or have a positive effect on those perceptions.

Research limitations/implications – Future research could usefully investigate the relative susceptibility of brands to non-collaborative co-creation, the effects on brands of higher complexity than those in our experiment, exposed in higher-involvement media, and the effects of more diverse forms of co-creation.

Practical implications – Brand managers must recognise that co-creation carries considerable risks for brand equity. They should closely monitor and track the first signs of non-collaborative co-creation in progress. It could be beneficial to recruit artists as co-creators of controlled brand play.

Originality/value – This study offers a more complete insight into the effect of non-collaborative co-creation on observers’ perceptions of brand equity than so far offered by the existing literature. It connects the fields of brand management and the arts by investigating the role and impact of artists as collaborative or non-collaborative co-creators of brand equity.

Keywords Brand equity, Artist co-creators, Brand attack, Brand play, Non-collaborative co-creation

Introduction

One view of branding is as a dynamic social process constructed through multiple relations between companies and stakeholders, for instance, Merz et al. (2009), Veloutsou (2009), Vallaster and Von Wallpach (2013), Kaufmann et al. (2016) and Von Wallpach et al. (2017). The outcome of active dialogue and interaction between the integrated parties is “co-creation” of the brand’s value and meaning (Iglesias et al., 2013; Black and Veloutsou, 2017). Most published studies in the field of brand co-creation tend to take an optimistic perspective of consumers engaging with each other and with the brand, a process which has become a key objective in the marketing strategies of many companies (Dessart et al., 2015). However, the involvement of consumers in the creative and innovative co-creation processes around branding entails the risk of negative forms of engagement (Hollebeek and Chen, 2014). Brand co-creation can mean that companies lose control over the brand’s meaning (Cova and Paranque, 2016; Saleem and Iglesias, 2016), which may be pushed in unwanted directions (Ind, 2014). Co-creators could misuse their increased empowerment by behaving non-collaboratively.
instead of as valuable contributors and thereby representing an uncontrollable source of information (Black and Veloutsou, 2017). Both the existing literature and real-life cases suggest that non-collaborative co-creators may either playfully parody initial brand meanings or express negative emotions they feel towards the brand and its meanings (Fournier and Avery, 2011; Zarantonello et al., 2016; Hegner et al., 2017).

In real-world cases, the entries in an online label design competition in 2011 backfired for the German dishwasher detergent brand Pril. Among non-serious and facetious designs and slogans, one included the headline “Tastes of chicken”, and another featured a distorted cartoon face (how-todotcom, 2011). A similar competition for the Nutella brand in France attracted submissions containing a number of words to which the brand owner seriously objected, such as “palm oil” or “orangutan”. Provoked by what was seen as censorship, contestants turned to negative and harmful word-of-mouth (Theeboom, 2015). Both brands were thus facing the consequences of non-collaborative co-creative behaviour, which certainly did not work to their own advantage. The literature normally focusses on consumers as the co-creators of brand meaning subversions, but also acknowledges that professional artists are often the originators of brand-related parodies and anti-brand content (Klein, 1999; Sandlin and Milam, 2008; Borghini et al., 2010). Specific cases include a German artist known for his gentle mocking of brand names and logos, Petrus Wandrey, who transformed Nivea Crème into “Naive Crème” and Rolex into “Relax” (Petrus-wandrey.com, 2015), and the American artist Ron English, who explicitly attacks brands rather than playfully distorting logos or designs. Blazenhoff (2012) reports his re-naming a Kellogg’s cereal as “Sugar Frosted Fat from Killkids” and picturing the brand’s mascot Tony the Tiger as an overweight “Fat Tony”.

Although such brand parodies and negativity towards brands are a current and developing phenomenon (Fournier and Alvarez, 2013; Rauschnabel et al., 2016; Veloutsou and Guzman, 2017), research has so far paid very little attention to the brand-related effects of non-collaborative co-creation. Non-collaborative behaviour has been identified, however, as a significant feature of interactions between a brand owner and its stakeholders (Echeverri and Skalen, 2011; Gebauer et al., 2013; Greer, 2015) with the attendant danger that altered brand meanings can start to compete with those initially created by brand managers and thereby decrease the value of hitherto successful and competitive brands (Thompson et al., 2006; Giesler, 2012; Cova and D’Antone, 2016). In such a situation, co-creation is not a process of mutual brand value development, but becomes one of brand meaning destruction (Gyrd-Jones and Kornum, 2013). If so, non-collaborative co-creation is a serious threat to a brand and its carefully nurtured equity. There is therefore an urgent need to explore the ways in which the results of non-collaborative co-creation are perceived in the marketplace. Our paper accordingly presents what is to the best of our knowledge the first empirical attempt to investigate the effect of that one form of co-creation on brand equity as perceived by the observers of the co-created content. We define that perception as “observer-based brand equity” or OBBE. Our study also tests the extent to which the effect on OBBE is moderated by the particular form of non-collaborative co-creation, on the grounds that such distinct forms might have a totally different effect on the brand and that their potential damage to its equity could therefore differ significantly, as well as the consequent need for the brand owner to react appropriately. In one such form, the brand may serve as a fodder for parody and pranks (Harold, 2004; Thompson et al., 2006; Fournier and Avery, 2011); we call this “brand play”. In another form of non-collaborative co-creation, the brand is hijacked for a destructively negative re-imagining of its meanings (Cova and Pace, 2006; Romani et al., 2015; Zarantonello et al., 2016); we call that “brand attack”.

A second moderator explored in the study is the type of co-creator, specifically general consumer or independent artist. Artists do regularly engage in non-collaborative co-creation (Klein, 1999; Borghini et al., 2010), and we may suppose that the effect they have on OBBE will differ from that exerted by mainstream consumers. Research studies having furthermore shown that art has a positive effect on brands (Hagtvedt and Patrick, 2008a; Fuchs et al., 2013; Lee et al., 2015), we explore the extent to which that also holds true in the case of non-collaborative co-creation.

Our findings are as follows:

- Non-collaborative co-creation can lead to a dilution of brand equity even for high-equity brands, demonstrated by a before-and-after negative change in OBBE.
- Its effect is moderated by the form of non-collaborative co-creation and type of co-creator.
- Artists can influence brand equity positively even if the artwork is the result of non-collaborative co-creation behaviour.

These findings can help academics and practitioners alike to better understand the dangers and risks inherent in brand co-creation. Specifically, they offer guidance on when to take action against destructive non-collaborative co-creation and how to engage artists in the branding process constructively.

**Conceptual background and development of hypotheses**

**Co-creation of brand meaning**

Consumer co-creation challenges traditional company-centric approaches to management. A company is no longer the sole creator of value but shares that task collaboratively with its stakeholders (Prahalad and Ramaswamy, 2004). The co-creation idea is strongly rooted in innovation and new product development (Ind and Coates, 2013). More precisely, the traditional innovation paradigm views consumers as passive entities who are largely dependent upon firms to help satisfy their needs. This perspective has been challenged by, for instance, Von Hippel (2009), while the growing empowerment of consumers to co-produce products and services with other consumers and with the brand owners has been recognised by Chang and Taylor (2016). Co-creation in NPD focusses on collaborative interactions between integrated parties. Enthusiastic consumers who are well disposed towards a brand become involved with it and support the brand owner in developing and evaluating innovations (Cui and Wu, 2016). The generally positive tenor of findings in innovation management research has strongly influenced the application of the co-creation perspective to other fields such as branding.
and to the optimistic level of discussion of co-creation in the brand management context.

The notion of brand co-creation is founded upon the proposition that a brand can no longer be defined simply as a representation of a product or service but must rather be understood as the perceptions and interests that unite a disparate group of stakeholders in the pursuit of common cause (Hatch and Schultz, 2010). The literature of branding has simultaneously progressed from the perspective of brands as markers of identification and means of product differentiation to a dialogue discussing brands in terms of a complex social process allowing for the co-creation of value and meaning by multiple stakeholders (Ind et al., 2013; Gyrd-Jones and Kornum, 2013; Kaufmann et al., 2016; von Wallpach et al., 2017). The notion of co-creation posits that instead of accepting the brand owner’s view of what its brand is, consumers and other stakeholders act as joint creators and active conduits of brand meaning (Vallaster and von Wallpach, 2013), which incorporates both its identity and its reputation of the brand (Black and Veloutsou, 2017). Stakeholders thus have the power to divert a brand’s internal positioning and its external identity and image in totally new directions.

Academic studies of co-creation, including those focussing specifically on brands, have so far tended to neglect the intuitively reasonable proposition that possible negative outcomes must exist. Their perspective is clearly optimistic, emphasis being placed on the product-related and brand-related benefits of co-creation and potential risks combined with customer integration stay overlooked. In fact, non-collaborative behaviour has been identified as a significant feature of interactions between brand owners and stakeholders, capable of inhibiting a positive co-creation strategy (Echeverri and Skalen, 2011; Gebauer et al., 2013; Greer, 2015). Co-creation thus becomes a process of mutual destruction of brand meaning rather than one of mutual brand development (Gyrd-Jones and Kornum, 2013).

Co-destruction of brand meaning

The process of brand co-creation has been most thoroughly explained in academic studies of brand communities in which individuals establish relations with each other and with the brand to co-create the brand’s meaning, for example, Muniz and O’Guinn (2001), Cova and Pace (2006), Veloutsou (2009) and Dessart et al. (2015). A separate research stream in the literature has shown that brand meanings can be co-destroyed in geographically independent “anti-brand communities” made up of individuals who are opposed to brands (Hollenbeck and Zinkhan, 2006, 2010; Cova and White, 2010; Dessart et al., 2016; Popp et al., 2016), the existence of which is said to be an example of the growing negativity towards brands (Veloutsou and Guzman, 2017). The literature has recently acknowledged that consumers can indeed dislike brands (Demirbag-Kaplan et al., 2015) and sometimes even feel “hate” for them (Zarantonello et al., 2016; Hegner et al., 2017). It has in fact been argued that such negative relationships with brands are even more common than the positive alternative, and that co-creation as a tactic for brand building is strongly driven by risk (Fournier and Alvarez, 2013). Negative forms of engagement with a brand, as reported for example by Hollebeek and Chen (2014) call into question the optimistic paradigm of peaceful collaborative creation, emphasising instead that co-creation can seriously endanger brand equity.

Another distinct mechanism for transforming initial brand meanings in unwanted directions is “culture jamming”, an increasingly popular activity that can be understood as social protest against a consumption-oriented culture and the influence of commercial mass-media (Klein, 1999; Kozinets and Handelman, 2004; Sandlin and Milam, 2008). Its proponents distort and re-define the cultural symbols that are most often represented by successful and iconic brands (Romani et al., 2015). Culture jamming takes many distinct forms, such as the subversion of advertisements and parodying of websites. Exponents may even shoplift an item, change its labelling or packaging and return it to the shelves (Sandlin and Milam, 2008). The most prevalent manifestation of culture jamming is so-called “adbusting”, often carried out by independent artists, the aim of which is to create “adversarial” brand meaning by publishing and distributing “anti-advertising” (Rumbo, 2002). While anti-brand communities are clearly related to anti-branding and negativity towards brands, culture jamming also contains the notion of brand-related parodies and pranks that are playful rather than confrontational (Harold, 2004; Fournier and Avery, 2011). Their aim is to “improve” meanings to force a change, rather than to destroy them (Klein, 1999).

Anti-brand communities and culture jamming are clear cases-in-point of the general phenomenon of non-collaborative co-creation in action, in our context with respect to brand imagery, brand meaning and brand equity. Though such co-creation is not necessarily negative just because it is “non-collaborative”, our study is concerned with the scenario in which a brand owner’s stakeholders misuse their increased empowerment in the process and do not integrate their resources in the way the company expects. Drawing upon the notion of “devaluation of value” (Plé and Chumpitaz Cáceres, 2010), we can characterise non-collaborative brand co-creation as the collaborative co-destruction of brand value. The very fact that external actors may become involved in the branding process means that while a company can plan and manage a strategy for brand identity, it cannot be in full control of public perceptions of the brand’s meanings (Saleem and Iglesias, 2016; Cova and Parangue, 2016). That fact brings with it challenges and risks, given that the commercial interests of the organisation can come into conflict with the intrinsic motivations of consumers and other stakeholders, who may want to steer the brand in directions unwanted by the brand owner (Ind, 2014). This process fosters brand-related parodies and what Thompson et al. (2006) and Giesler (2012) have described as “doppelganger images” capable of diluting brand meanings and endangering a brand’s equity. As most of such co-creation takes place in online networks (Vallaster and von Wallpach, 2013), altered brand meanings diffuse rapidly and thereby increase the possible danger of non-collaborative behaviour.

To the best of our knowledge, there is no available empirical research into non-collaborative co-creation while the majority of studies in closely related fields, such as anti-brand communities and culture jamming, have majored on qualitative research (Romani et al., 2015). Bearing in mind the potential risks of such co-creation for a brand (Fournier and Alvarez, 2013), our
study aims to close a gap in current knowledge with regards to
the effect of non-collaborative co-creation on brand equity by
studying the process experimentally. Given that brand equity is
now considered to be a key asset for almost any firm in the mass
market and has become a key concept for marketing academics
(for example Christodoulides et al., 2015; Chatzipanagiotou et al., 2016), OBBE emerges as the most appropriate measure of
the effect. Our study is particularly concerned with investigating
how observers in the marketplace perceive the results of non-
collaborative co-creation. In the process of co-creation, the
overall brand equity is made up of the equity of a small fraction
of active participants who agree to engage in the process and a
large proportion of passive observers who heavily outnumber the
former (Fuchs et al., 2013; Kristal et al., 2016).

Dilution of brand equity by non-collaborative brand
cocreation
A key proposition underpinning our study is that non-
collaborative co-creation has a negative effect on OBBE. We
believe that this effect is caused by a dilution of brand equity,
as demonstrated by a negative difference in before-and-after
OBBE values, a measure previously applied by Pullig et al.
(2006) and Bambauer-Sachse and Mangold (2011) to the same
phenomenon. In our study, dilution is operationalised as a
response to negative cues communicated by specific cases of
non-collaborative co-creation: specifically, distorted brand
logos and advertising images that trigger constructive
processing of information in a way that may revise initial beliefs
about the brand and bring about a weakening of important
brand value perceptions (Fournier and Alvarez, 2013). An
inconsistency could thus emerge between those initial beliefs
and the distorted and deformed brand imagery (Keller, 2003).
Specifically, altered meanings challenge initial meanings; there
is a good chance that observers will revise their initial brand
evaluation towards the non-collaborative co-creation, and a
dilution of OBBE will potentially result.

Our first research hypothesis is thus that:

H1. Non-collaborative behaviour of co-creators has a negative effect on OBBE.

This proposition may at first sight seem intuitively obvious, but
we contend that there is an urgent need to examine it
empirically, first because this type of co-creation has not yet
been formally investigated and its effect on brand equity is
therefore unclear, and second because one form that it
commonly takes in practice is culture jamming, the playful
parodying of brand meanings. Fournier and Avery (2011) have
argued that such parodies can in fact be an indication of much-
coveted cultural resonance for original brand meanings. It
could thus be the fact that they would increase brand
awareness, a benign or even positive outcome for the brand,
and ultimately mitigate the expected negative effect on OBBE.

Different forms of non-collaborative brand co-creation
The literature suggests that there are two forms of non-
collaborative brand co-creation, which can be detected in real-
life scenarios: the phenomena we have called brand play and
brand attack. It was essential to test both in our study because
their effect on OBBE is unclear and the need is to capture the
overall effect of non-collaborative co-creation.

Brand play can be recognised when the brand is used as a
fodder for parody. It has its roots in culture jamming and the
playful creation of parodies. The concept of playfulness has
been studied extensively in marketing-related research as a
possible response to advertising (Alden, 2000). It has been
noted that it is strongly associated with the application of
humour to advertising (Rössner et al., 2017), and that a positive
connotation is attached to it (Aaker et al., 1988). Playful
subversion of a brand might create a positive and risk-free
culture for observers (Fournier and Avery, 2011), but could,
on the other hand, generate a disconnection between actual
brand beliefs and perceived brand attributes, thereby leading to
a revision of initial brand meanings. We compare this situation
with an unsuccessful brand extension in which the extension
attributes are inconsistent with beliefs regarding the family
brand (Roedder-John et al., 1998). Our assumption is that this
inconsistency will lead to a dilution of OBBE. The second
form of non-collaborative brand co-creation is, by contrast, a clearly
derisive and aggressive way of subverting a brand, for example,
by criticising the brand owner’s corporate practices, such as the
exploitation of child labour and sweatshops; we call that brand
attack. Hegner et al. (2017) argue that this form is strongly
related to negative emotions with regards to brands and to anti-
branding. Tanner et al. (1991) and Alden et al. (2000) suggest
that attacking a brand’s meaning can actually engender
fearfulness, especially if the brand is depicted in a threatening
culture. Brand attack and the reaction to it is seen as a brand-
related adverse event by Dutta and Pullig (2011), who link it to
a brand crisis. This can not only have devastating general
consequences for the brand (Dawar and Pillutla, 2000) but also
dilute its equity (Fournier and Alvarez, 2013). We therefore
believe that both brand play and brand attack have a negative
effect on OBBE and cause its dilution, the effect of the latter
being expected to be stronger than that of the former.

Our second research hypothesis is thus that:

H2. The form of non-collaborative brand co-creation
moderates the effect on OBBE.

Artists as non-collaborative brand co-creators
The literature also concerns itself with artists, rather than
mainstream consumers, as a significant category of non-
collaborative co-creators (Klein, 1999; Borghini et al., 2010).
Various cases in point show how they may distort brand logos
and graphic images by either brand play or brand attack, as
exemplified, respectively, by the non-collaborative co-creations
of Petrus Wandrey and Ron English described in the
Introduction.

Increasingly, brand owners actively seek to join forces with
the arts, while an increasing number of artists are cooperating
with commercial organisations beyond the art world (Iezzi and
Weaton, 2007). There is general agreement that consumers
perceive art differently from how they perceive other objects
(Joy and Sherry, 2003). In recent years, some studies have
begun to investigate the use of art as a marketing tool. The “art
infusion hypothesis” (Hagtvand and Patrick, 2008a) asserts that
the integration of art has a positive effect on the image of a
product or a brand, whether the artwork is evaluated positively or negatively by consumers; it is the fact of integrating art and commerce that exerts the influence. It can also have a positive effect on a brand’s perceived extendibility (Hagtvedt and Patrick, 2008b) and may furthermore enhance perceptions of its prestige, quality, value and uniqueness. This positive effect can occur whether consumers are familiar with the artist (Lee et al., 2015). It was found by Lacey et al. (2011) that imagery associated with “art” was preferred to that associate with similar images that were visual but not classified as art. They argue that whatever their content and form, such visual stimuli operate upon the area of the brain connected with rewarding experiences, evoking positive feelings and emotions. Research has also found that art can have a beneficial effect on corporate reputation and image, especially if the company sponsors cultural activities and institutions and announces the fact to the public (Quether and Thompson, 2001; McNicholas, 2004; Schwaiger et al., 2010), and that purchase intention and customer loyalty increase when companies are committed to sponsoring the arts (Carrillat et al., 2008; Mermiri, 2010).

In the literature, artist co-creators are described as being socially distanced from mere participants in co-creation campaigns. To counter the mitigating effect of co-creation on the image of luxury brands, Fuchs et al. (2013) proposed a strategy to “legitimise” those consumers who were part of the co-creation activity. They found that observers rated user-designed luxury brands more positively if the co-creators were socially distanced to some extent from average consumers by being described as “artists”. So, in general, it seems likely that any individual who has been presented as a legitimate influencer can have a positive effect on observers’ evaluation of the brand. Artists can exert that influence in particular because of their social distance from other consumer co-creators and mere observers. Thanks to their superior experience and expertise in design processes, artists can be declared as “experts”, who will be credited with the ability to perform product-related tasks in a specific area more successfully and skilful than novices (Jacoby et al., 1986; Alba and Hutchinson, 1987). Marketers may be able to convey messages more effectively by working with experts as spokespeople for a product or a brand because the persuasiveness of the message is increased and consumers feel more confident during the purchase and consumption process (Atkinson and Rosenthal, 2014).

Based on the positive effect of art on a brand and harnessing the idea that mere consumers could rate artists as experts, we assume that non-collaborative brand co-creation by consumer co-creators results in a stronger dilution of OBBE than co-creation by artist co-creators.

Stating that proposition as a formal research hypothesis:

H3. The type of co-creator moderates the effect on OBBE.

The conceptual framework in Figure 1 summarises the relationships postulated in the three research hypotheses.

**Empirical study**

**Sampling**

Brand co-creation mostly takes place online (Fournier and Avery, 2011; Kennedy, 2017), and the millennial generation accounts for as much as 90 per cent of social media users (Duggan et al., 2014), the majority of those being students. Thus, it is students who mainly engage in brand co-creation and who are typically exposed to the results of co-creation activities. Also, people born between 1982 and 2000 now represent more than a quarter of the population in the USA (Kennedy, 2017), constituting crucial target groups globally for the brands chosen for the pilot study, pre-tests and main study. If any research findings are to be applicable to consumers of a specific product category or specific brands, then the research should sample those people (Calder and Tybout, 1999). Therefore, a student sample was a proper choice as such a sample is representative of a population of interest in the context of our study. From a statistical point of view, students enhance research validity on account of their apparent homogeneity (Peterson and Merunka, 2014). The resulting high level of internal validity plus the reduced extraneous variability in data allow for strong hypotheses tests to be conducted (Calder et al., 1983; Peterson, 2001). This was considered to be a particularly important consideration for the design of our study because the effect of non-collaborative brand co-creation on OBBE has never been tested before: the effect could prove to be small and a beta error could therefore discourage further research into the phenomenon in future. Our study was in fact concerned more with the testing of theory than with the generalisation of results to other population groups. To ensure that testing was both rigorous and powerful, the sample needed to be as homogeneous as possible. The homogeneity within student samples is essentially higher than within other homogeneous or non-homogeneous samples (Calder et al., 1983; Calder and Tybout, 1999; Peterson, 2001; Reynolds et al., 2002).

**Pilot study**

A pilot study was conducted to inform the selection and design of the two implementations of non-collaborative brand co-creation to be tested: “brand play” and “brand attack”. In total, 19 students of business administration and economics at a German university were exposed to a dossier of 29 representations of well-known brands, from varying product categories and different levels of complexity, all of which had been distorted in some way by individuals exposed to them in the marketplace. They were asked to say if the motivation of the consumer co-creators seemed to them to be to play with the brand or attack it. The first of those alternatives would correspond to such descriptions as “playful”, “humorous”, “silly”, “ironic” or “youthful” and the second to “attacking”,

![Conceptual framework](figure1.png)
“Brand play” versus “Brand attack”

Samuel Kristal, Carsten Baumgarth and Jörg Henseler

The second pre-test adopted tried-and-tested scales for measurement of the effectiveness of a second independent variable, whether the co-creator was a consumer or an artist. Based on the mean values found in the first pre-test, we chose the Nike and Levi’s brands to be the stimuli. We furthermore created purpose-written newspaper stories about the co-creation of the logos and graphic treatments presented to the participants. One reported that co-creators, either consumers or artists, had spontaneously distorted the Nike logo and visual in the two different ways shown in Appendix and disseminated the result online. The other explained that Levi’s had instigated the co-creation process by running a competition and that those “integrated” consumer or artist co-creators had chosen to attack the brand by distorting those elements in one of the two ways shown in Appendix, rather than simply playing with them. The articles confirmed the “artist” status of the co-creator by reporting that he had exhibited in the previous year at the Museum of Modern Art in New York and was famous for distorting the graphic representation of iconic brands. Participants in this pre-test were 45 undergraduate students of business administration, 26 of whom were female. They read the article on the first brand before seeing the distorted visual image and then responding on a Likert scale anchored at 1 = totally disagree and 5 = completely agree to the statements “This graphic treatment of the brand is art” and “The co-creator is an artist”, adopted from a study by Hagtvedt and Patrick (2008a). They then repeated the procedure for the second brand. The results showed that the manipulation of co-creator type had been effective. In the case of the brand play treatment for Nike (artist co-creator against consumer co-creator), the distorted logo and transformed strapline seen in Appendix were evaluated as art (4.18 > 1.81; p = 0.00) and the creator as an artist (4.27 > 2.09; p = 0.00). For the brand attack alternative (artist co-creator against consumer co-creator), in which the “swoosh” logo was unaltered but the strapline was clearly polemical, the treatment was again evaluated as art (3.63 > 1.66; p = 0.01) and the creator as an artist (3.72 > 1.83; p = 0.00). With regard to Levi’s, the brand play treatment (artist co-creator against consumer co-creator), involving an anagram of the brand name and an image of Elvis Presley, as also shown in Appendix, the treatment was assessed as art (3.83 > 1.54; p = 0.00) and the creator as an artist (4.25 > 1.72; p = 0.00). In the brand attack variation in which the brand logo was intact but the visual unarguably hostile, the treatment was once more seen as art (3.72 > 1.63; p = 0.00) and the creator as an artist (4.18 > 1.54; p = 0.00).

Study

In the mixed design of our study, the within-subjects factor was elapsed time and the 2 × 2 between-subjects factors were formed (brand play versus brand attack) and typed (consumer as co-creator versus artist as co-creator). The F-tests were Greenhouse–Geisser adjusted. The 255 participants in the main study were students at a German university, three quarters of whom (76 per cent) were studying Business Administration and Economics; their average age was 23 and 60 per cent were female. Though it would be risky to generalise such a specific sample, a significant proportion of users of Levi’s and Nike products are indeed of student age. With that proviso, the findings presented in the next sub-section are an

Aaker et al., 1988; Alden et al., 2000. After identifying those logos which looked unfamiliar and could not be associated with any brand, participants allocated each of the remainder to one of three groups by writing “P” (brand play), an “A” (brand attack) or a “?” (not sure) on the image itself. Of the 29 brands, 7 were classified as either P or A.

Pre-tests

While the approach of the pilot study was exploratory, the objective of first of two pre-tests was to develop scales for the measurement of one independent variable, the form taken by non-collaborative brand co-creation: play versus attack. We used Adobe Photoshop to design a “counterpart” for each of seven logos and graphic treatments which had survived the pilot study. The counterpart of one designated A for brand attack was manipulated to depict brand play, and vice versa. As the notion of play is closely associated with the concept of humour, the play alternatives were treated humorously. The brand attack classification being related to brand-adverse events, our distorted creative treatments were associated with child labour. Examples of the distorted alternatives for two of the seven brands are shown in Appendix.

The scales for the measurement of play and attack were based on the work of Aaker et al (1988) and Alden et al. (2000). Specifically, in the case of play, they were seven scale items (funny, playful, humorous, childish, silly, zany and youthful); for the attack variant, the scale comprised six items (fearful, attacking, destroying, threatening, aggressive and irritating).

We allocated 38 undergraduate students of business administration, 21 of whom were female, between two subsamples which would be exposed to either the play or attack manipulation. A recording schedule presented them with one or other of the two treatments, the corresponding seven or six scale items, and rating scales anchored at 1 = totally disagree and 5 = completely agree. Exploratory factor analysis found that, in the case of brand play measurement, two items loaded on a second factor: “childish” and “silly”. Those were duly eliminated. Brand attack loaded on a single factor. The reliability of the scales was confirmed by Cronbach’s α coefficients of 0.876 for brand play and 0.915 for brand attack.

original empirical attempt to capture the effect of non-collaborative co-creation on brand equity.

The experimental procedure comprised before-and-after measurement of OBBE with a period of unrelated activity sandwiched between the two measurements. In the before phase, participants were given a dossier containing non-manipulated treatments of advertisements for Nike and Levi’s and also for the German chocolate brand Milka, an extra stimulus placed in the middle of the dossier to distract them from the exact purpose of the study. OBBE was measured for all three brands to capture the baseline brand equity of each. Completion of the “before” measurement scales was followed by 45 min of “filler” activity unrelated to the experimental scenarios, the purpose of which was again to deflect attention from the exact purpose of the experiment.

For after-measurement of OBBE, participants were given a second dossier containing the pre-tested manipulated versions of the visual treatments and newspaper articles relating to Levi’s and Nike, attributed to the intervention of an artist or a consumer, plus non-manipulated Milka stimuli and an entirely neutral newspaper article. They completed the same rating scales as before, measuring their perceptions of the brand equity of Nike, Levi’s and Milka in the various experimental conditions described.

The particular focus of the main study was the dilution in OBBE, which would be demonstrated by a negative difference in before-and-after values for OBBE, as in studies by Pullig et al. (2006) and Bambauer-Sachse and Mangold (2011).

Table II shows the 11 different items chosen to measure the dependent variable OBBE, which have been used in a recent study by Kristal et al. (2016). Those are derived from scales for the measurement of OBBE in several earlier studies (Yoo and Donthu, 2001; Atilgan et al., 2005; Bravo Gil et al., 2007; Lehmann et al., 2008). The reliability of the current scale was confirmed for both brands in the before and after measurement by the Cronbach’s α coefficient (Levi’s before = 0.908; Levi’s after = 0.939; Nike before = 0.858; Nike after = 0.954).

The effectiveness of both manipulations was checked again for the main study by the same measures as in the pre-tests. T-tests showed the effectiveness and significance of the form of non-collaborative brand co-creation: Nike after (4.45 play > 4.53 attack; p = 0.00); Nike before (4.15 attack > 1.40 play; p = 0.00); Levi’s after (3.35 play > 1.38 attack; p = 0.00); Levi’s before (4.27 attack > 1.26 play; p = 0.00); they also confirmed that variation between artist and consumer co-creation and the manipulation of the art work were significant for both brands: Nike artist vs consumer (4.06 > 2.17; p = 0.00) – Nike art work vs no art (3.67 > 2.11; p = 0.00); Levi’s artist vs consumer (3.84 > 1.95; p = 0.00) – Levi’s art work vs no art (3.51 > 2.07; p = 0.00).

Findings

A repeated-measures ANOVA tested the postulated framework, finding that there was a significant pre-post difference in OBBE values for Levi’s and Nike. H1 can be accepted for both brands as non-collaborative co-creation affected OBBE negatively, as shown in Figure 2. In the case of Nike [F (1,242) = 101.139, p = 0.000], the extent of dilution was 0.61 (OBBE before 4.19 > OBBE after 3.58); for Levi’s [F (1,246) = 138.877, p = 0.000], it was 0.63 (OBBE before 3.84 > OBBE after 3.21). There was no interaction effect between the form of treatment or type of non-collaborative co-creator for either Nike [F (1,242) = 0.266, p = 0.606] or Levi’s [F (1,246) = 0.379, p = 0.379]. We can therefore proceed to the testing of the remaining hypotheses.

H2 was supported for both tested brands, so it can be stated that the form of non-collaborative co-creation does moderate the effect on OBBE. In the case of Nike [F (1,242) = 110.827, p = 0.000; $\eta_p^2 = 0.314$], in particular, brand play affected OBBE marginally. The dilution of −0.03 (OBBE before 4.16 < OBBE after 4.19) points to a slight positive effect of brand play on OBBE. The brand attack format caused a definite dilution of 1.23 (OBBE before 4.23 > OBBE after 3.00). For Levi’s [F (1, 246) = 70.378, p = 0.000; $\eta_p^2 = 0.222$], the dilution resulting from the brand play treatment was 0.16 (OBBE before 3.82 > OBBE after 3.66), while that attributable to brand attack was 1.13 (OBBE before 3.86 > OBBE after 2.73). H3 was supported for both brands, and it can therefore be stated that the type of co-creator type does moderate the effect on OBBE. The results for Nike [F (1,242) = 23.589, p = 0.000; $\eta_p^2 = 0.089$] were that believing the co-creator to be a consumer brought about a dilution of 0.94 (OBBE before 4.24 > OBBE after 3.30) and believing him to be an artist a figure of 0.25 (OBBE before

4.14 > OBBE_{after} 3.89). For Levi's [F (1,246) = 18.298, p = 0.000; \eta^2_p = 0.069], belief in a consumer co-creator resulted in a dilution of 0.92 (OBBE_{before} 3.82 > OBBE_{after} 2.90), while the value if the co-creator was presented as an artist was 0.36 (OBBE_{before} 3.85 > OBBE_{after} 3.49).

The dilution measured in the four sub-groups is shown in Table III. In the case of the brand play treatment of Nike, representing it as the work of a consumer co-creator led to a dilution of 0.22 (OBBE_{before} 4.25 > OBBE_{after} 4.03), while the belief that it was the work of an artist resulted in a value of −0.28 (OBBE_{before} 4.07 < OBBE_{after} 4.35). These results indicate a before-and-after diminution and improvement in OBBE. The combination of brand attack and non-collaborative co-creation by a consumer resulted in a dilution of 1.49 (OBBE_{before} 4.23 > OBBE_{after} 2.74); the value for the artist co-creator was 0.87 (OBBE_{before} 4.22 > OBBE_{after} 3.35). With respect to Levi's, dilution brought about by the brand play treatment being attributed to a consumer co-creator was 0.38 (OBBE_{before} 3.80 > OBBE_{after} 3.83). There was no measurable dilution if the co-creator was said to be an artist (OBBE_{before} 3.83 = OBBE_{after} 3.83). The brand attack treatment attributed to a consumer co-creator resulted in a dilution of 1.39 (OBBE_{before} 3.85 > OBBE_{after} 2.46); when the co-creator was believed to be an artist, the dilution was 0.83 (OBBE_{before} 3.87 > OBBE_{after} 3.04).

### General discussion

#### Theoretical implications

The academic literature contains a large corpus of research on the beneficial effects of co-creation on the product or the brand. It does not, however, offer sufficient evidence of consequences and brand-related effects if co-creation “goes wrong”. The findings of our study confirm the theoretical proposition that the phenomenon of co-creation of a brand entails loss of control to some extent over public perceptions of the brand’s meanings, which can be steered in directions unintended by an original branding strategy.

Our study identified, described and defined the phenomenon of non-collaborative co-creation to clarify the process by which brand meanings can be subverted during co-creation. In particular, we conceptualised two forms of co-creation: *brand play* as the playful parodying of brand meanings, as suggested by Fournier and Avery (2011), and *brand attack* as the expression of negative emotions or even hate for the brand, as identified by Demirbag-Kaplan et al. (2015) and Hegner et al. (2017). Our study joins a small number of others to explicitly analyse the effect of negative co-creation, for example, those by Echeverri, and Skalen (2011), Gebauer et al. (2013) or Greer (2015). It is the very first, to the best of our knowledge, to explore how that affects observers’ perceptions of brand equity. Our findings can be extremely valuable, given that the creation of brand-related parodies and the expression of negativity

</table>
towards brands together represent a current and developing trend in co-creation (Fournier and Alvarez, 2013; Cova and D’Antone, 2016; Veloutsou and Guzman, 2017). Our study shows that co-creation which goes wrong is strongly driven by risk-affecting brands in general and high-equity brands in particular. Brand meanings created by non-collaborative co-creators are starting to compete with the brand meanings that brand managers have set out initially created through their branding strategies. Thus, in contrast to the characteristically positive tenor of brand co-creation studies, we have come to a contrasting conclusion with regards to its effect. We found that a “brand attack” co-creation mode caused a stronger dilution of OBBE than “brand play”, and that co-creation by consumers caused a stronger dilution than that executed by artists. To be precise, brand play by a consumer resulted in lesser before-after dilution of OBBE than brand attack by the same co-creator. The result of brand play by an artist was either a positive improvement in OBBE or no measurable effect at all. Our findings are therefore in line with those of previous studies on effects of art on brands, such as that by Hagstedt and Patrick (2008a).

Our study furthermore answers two specific needs identified by previous researchers: first, for more and better research on the inherent risks and dangers of co-creation (Plé and Chumpitaz Cáceres, 2010; Echeverri and Skalen, 2011; Gebauer et al., 2013; Greer, 2015); second, for more studies of independent observers of co-creation to extend the limited body of knowledge about their responses (Ind et al., 2013; Puchs et al., 2013).

Managerial implications
Co-creation marks a shift from management-oriented brand building to a collaborative process in which stakeholders become increasingly empowered. In its non-collaborative form, it can disrupt brand managers’ efforts to strengthen the brand and load it with powerful meaning. Subverted versions of those meanings can begin to compete with the original concepts communicated via marketing campaigns and generate what has been described in the literature as a “doppelganger” brand meaning (Giesler, 2012), which can potentially be caused by either brand play or brand attack and can lead to a significant dilution of observers’ evaluation of the brand’s equity. There is thus a strategic need for non-collaborative co-creation to be monitored and managed, especially when it takes the brand attack form and initial brand meanings begin to be damaged by virally dispersed unflattering brand meanings. Brand strategists must become familiar with viral environments, such as the blogosphere or brand communities, and monitor those regularly for evidence of anti-brand sentiments. IBM’s Social Sentiment Index, for instance, aggregates and gauges content from a range of social media platforms, distinguishing sarcastic and negative opinion from sincere and positive commentary and identifying such specific trends as critical and disruptive material (www.ibm.com, 2016).

However, echoing the conclusion of Popp et al. (2016) with respect to anti-brand communities, we propose that non-collaborative brand co-creation also sounds a wake-up call for brand managers to make the necessary improvements. Early warning of the subversion of brand meanings can provide strategists with insights that could be usefully applied to branding activities capable of strengthening the brand and thereby rendering non-collaborative behaviour beneficial for the brand and its meaning.

Brand-related parodies could be a sign of much-coveted cultural resonance for the original brand meaning (Fournier and Alvarez, 2013), particularly when they have been executed by artists. Our study has found that “brand play” initiatives executed by artists can have a positive effect on OBBE. We therefore advise practitioners to think about intentional cooperation with artists to the extent of suggesting that they playfully engage in brand co-creation. Many well-known companies do in fact invite artists to engage in various co-creation processes. For example, as long ago as 1975, BMW began to invite famous artists to propose their own model designs, which are exhibited in a company museum and at art exhibitions around the world; in 1985, the Swedish vodka brand Absolut invited Andy Warhol to play with the design of their bottle; in 2014, the luxury fashion brand Louis Vuitton opened its own art museum after a decade of involving artist and architects in the creation of limited editions, the design of their shops and other communications in general.

Limitations and further research
Although our study offers a more complete insight into how non-collaborative co-creation affects OBBE than can be gleaned from the literature to date, certain limitations need to be taken into account, which in turn suggest directions for further research.

The results of the analyses of the empirical data should be treated with appropriate caution, given that the participants in the study were university students, mostly studying business administration and economics. The risk of generalising from that sample is mitigated by the fact that students do represent a significant proportion of the target markets for the brands chosen to be the experimental stimuli. Also, our study was not concerned with the generalisability of our results to other populations but rather was focussed on theory testing with respect to an unknown effect; a highly homogenous sample was accordingly appropriate. Though the results could therefore be of interest and use to Nike and Levi’s, and to other companies targeting similar markets, it would nevertheless be advisable to replicate our study with a more heterogeneous sample.

Our paper has not commented on the dimensionality of value co-creation behaviour and its conceptual richness. Further research could usefully explore how value co-creation dimensions, particularly customer participation behaviour and citizenship behaviour, relate to an unsuccessful outcome of the co-creation process. It would be very valuable to focus on the role of customer behaviour in value co-creation to detect weaknesses in the process. Future research could investigate exactly what customer participation and customer citizenship behaviour need to look like so that the value co-creation process itself is successful (Yi et al., 2011; Yi and Gong, 2013). Such insights would also help strategists to understand which forms of co-creator behaviour lead to undesired outcomes.

Another issue for future research is the intensity of non-collaborative co-creation. In our study, participants read descriptions and discussion of the co-created material in (purpose-written) newspaper articles, which are generally considered to be a fairly a low-engagement medium. The effect on OBBE might possibly be greater if the experience and intensity of non-collaborative co-creation are stronger.
Consider the “Dismaland” project organised by the celebrated graffiti artist Banksy, a pop-up parody of an amusement park on a run-down site in a faded seaside resort in the south-west of England, featuring grumpy guards, funereal theme park games and negatively provocative artworks by about 60 international artists. Visitors walking through the creation were part of the experience. This high level of experience and the high-involvement nature of the non-collaboratively co-created images might be expected to intensify the effect, presumably negative, that they had on the visitor-observers.

With regards to artists as co-creators, it would be interesting to investigate whether payment for their participation yielded a different result in terms of OBBE from non-paid co-creation. In the scenario of our study, the artist co-creator was not engaged by the organisation but had subverted the stimulus materials without the company’s knowledge and consent. In practice, many companies today do purposely integrate artists into their creative and communicative operations with the express intention of benefiting the brand. A future study could test how independent observers perceive such paid-for integration of artists into promotion of a brand. Some might feel that payment removes the freedom and creativity, normally characterising art, and hence diminishes the positive effect of artist co-creators.

In our study, participants learnt about non-collaborative brand co-creation via newspaper articles. A future investigation could test whether the form of non-collaborative co-creation and the type of co-creator have a different potential to make the co-created material go viral and, if so, whether there would be a corresponding influence on the established effect on OBBE. For instance, brand attack might be more likely to be noticed by observers than brand play. Similarly, co-creation by artists might bring about a weaker dilution in OBBE than co-creation by consumers. However, if the work of the former reaches more observers online and offline than the initiatives of the latter, the more widespread perception of the subversion should also generate a stronger dilution.

Finally, our scenario invoked direct distortion of two brand logos and associated visual treatments. The possibility exists, however, that a brand might be used as metaphorical element on the basis of which to make a critical socio-political statement; the brand itself is not the primary goal of the attack, but only the means to an end. For instance, a painting by a Dutch artist depicted an obviously starving African boy holding a Louis Vuitton handbag and a chihuahua. The intention was that the juxtaposition of the handbag, symbolising Western affluence with African starvation would draw attention to the socio-political situation in Dafur. Similarly, the aim of a painting of a squashed Coca-Cola can by a Russian-German artist was not to attack the brand but to highlight pollution and the throwaway mentality of consumers. The question is whether such indirect brand attacks have any effect on OBBE and, if so, if the effect is any different from the results of our experiment.
